

BRAMERTON FILM NIGHT

In 2005, Dr. Mary Schweitzer and her team reported one of the greatest palaeontological discoveries in history: soft and pliable tissue was found within dinosaur bones. The scientific community was stunned, and many agreed that it IS not possible. They claimed it was contamination or bacterial biofilm merely mimicking soft tissue. However, during the past decade discoveries have continued and the evidence is stacking up.

What are the implications? Why does this matter? Because it challenges the evolutionary dogma at its very core. Come to the above film, see the evidence for yourself and understand why this is so important.
